REPORT No. RD.1136-R

Enclosed are two copies of a report on the NMFI test. As always, the establishment of tests developed elsewhere is not quite as straightforward as one would hope. Nevertheless, you will find that the relation between NMFI and long-term mouse skin results is similar to that found in Hamburg, while results for other JANUS series are included.

Some statistical analysis still has to be undertaken, while there are some additional reservations concerning the relevance of the test and the best form of the biological results to use for such correlations.

Despite these reservations the test should prove very useful as a preliminary screen for biologically oriented samples. It is already in use for this purpose.
